ACKNOWLEDGEMENTS

The acreage, yield, production, monthly, and season average value, and crop value statistics in this bulletin are official State and USDA estimates prepared by the Crop and Livestock Reporting Service. The county and area detail in these statistics were made possible by the participation of the Department of Agricultural Economics, University of Florida, in the estimating program. Market price quotations and shipment statistics are from the Market News Section and the USDA Consumer and Marketing Service. Other sources of data are cited in footnotes.

Agencies in the Florida Department of Agriculture providing basic data used in developing statistics in this summary include the Road Guard Section, Division of Inspection; State Markets Section, Celery Advisory Committee, and Sweet Corn Advisory Committee, Division of Marketing, the Plant Inspection Section, Division of Plant Industry and the South Florida Vegetable Exchange. County Agents of Florida's Agricultural Extension Service were very helpful in supplying information on vegetable production in their counties.

Growers, shippers, processors, sales agencies, and transportation firms voluntarily supplied much of the data used in developing these official statistics. This public spirited cooperation is appreciated.

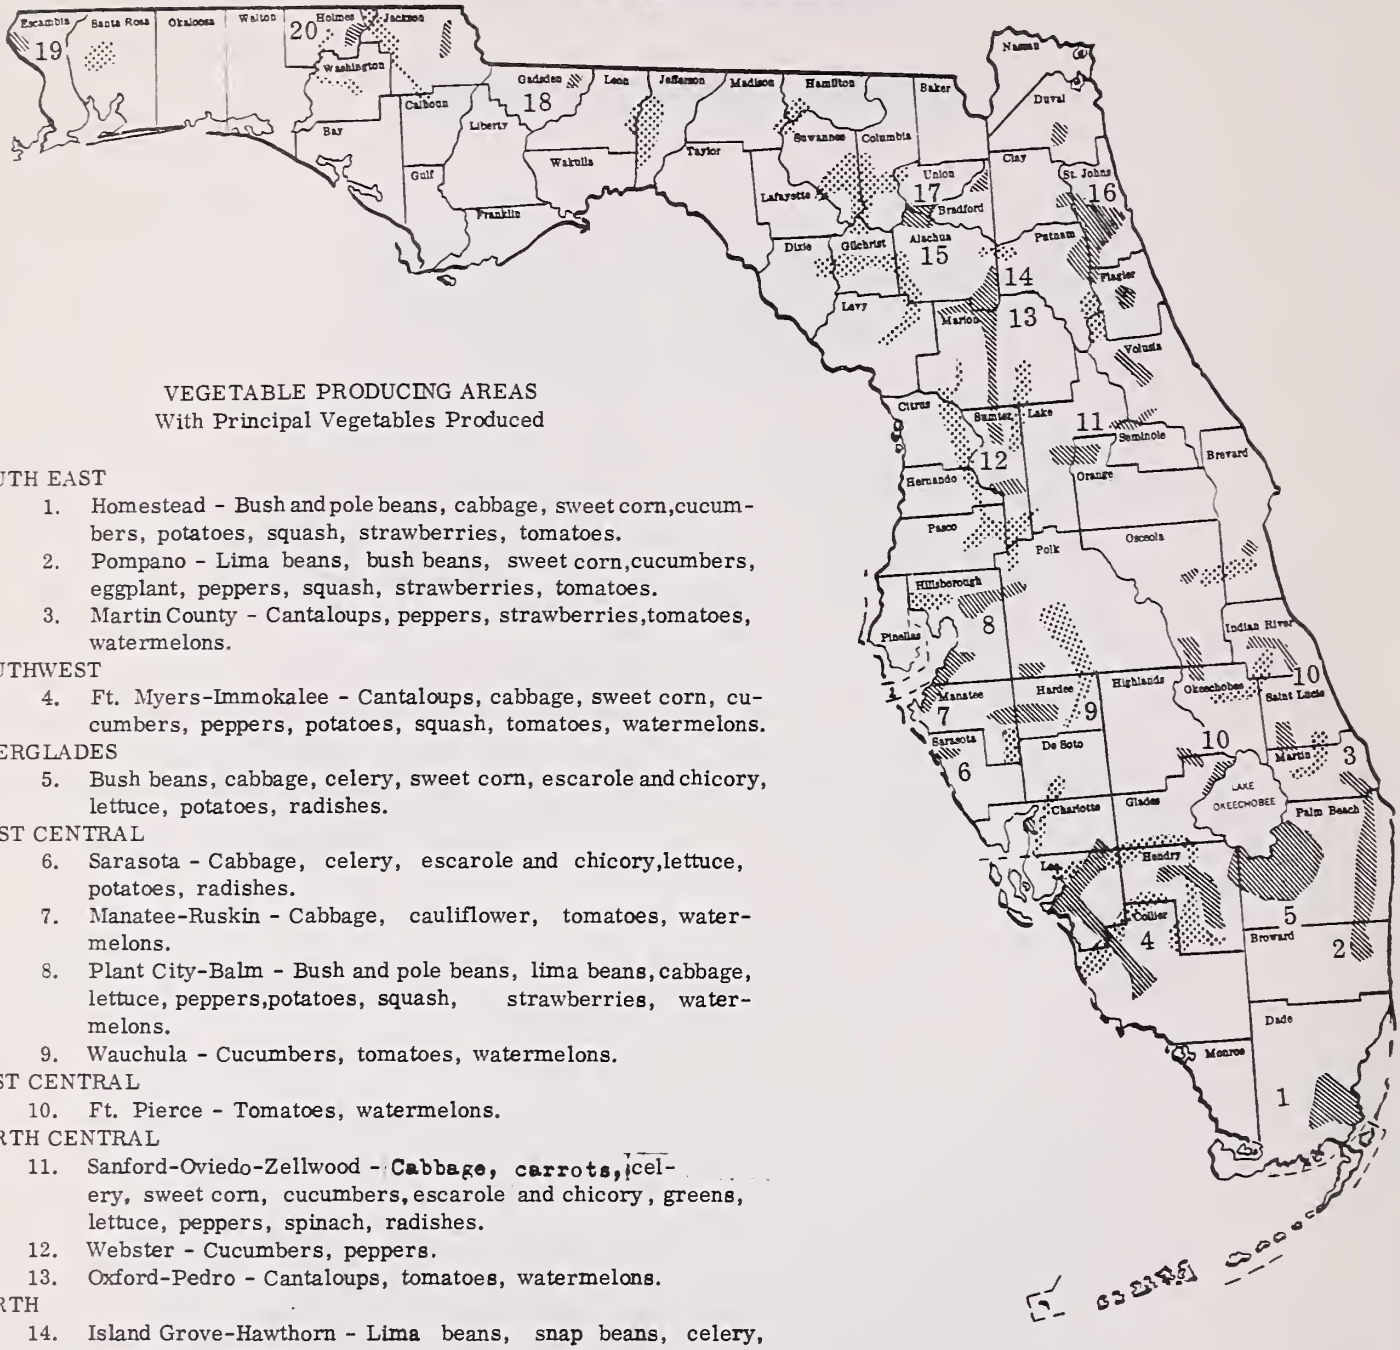
FLORIDA



VEGETABLE PRODUCING AREAS
With Principal Vegetables Produced

SOUTH EAST

1. Homestead - Bush and pole beans, cabbage, sweet corn, cucumbers, potatoes, squash, strawberries, tomatoes.
2. Pompano - Lima beans, bush beans, sweet corn, cucumbers, eggplant, peppers, squash, strawberries, tomatoes.
3. Martin County - Cantaloups, peppers, strawberries, tomatoes, watermelons.

SOUTHWEST

4. Ft. Myers-Immokalee - Cantaloups, cabbage, sweet corn, cucumbers, peppers, potatoes, squash, tomatoes, watermelons.

EVERGLADES

5. Bush beans, cabbage, celery, sweet corn, escarole and chicory, lettuce, potatoes, radishes.

WEST CENTRAL

6. Sarasota - Cabbage, celery, escarole and chicory, lettuce, potatoes, radishes.
7. Manatee-Ruskin - Cabbage, cauliflower, tomatoes, watermelons.
8. Plant City-Balm - Bush and pole beans, lima beans, cabbage, lettuce, peppers, potatoes, squash, strawberries, watermelons.
9. Wauchula - Cucumbers, tomatoes, watermelons.

EAST CENTRAL

10. Ft. Pierce - Tomatoes, watermelons.

NORTH CENTRAL

11. Sanford-Oviedo-Zellwood - Cabbage, carrots, celery, sweet corn, cucumbers, escarole and chicory, greens, lettuce, peppers, spinach, radishes.
12. Webster - Cucumbers, peppers.
13. Oxford-Pedro - Cantaloups, tomatoes, watermelons.

NORTH

14. Island Grove-Hawthorn - Lima beans, snap beans, celery, squash, watermelons.
15. Gainesville-Alachua - Bush beans, cucumbers, peppers, potatoes, squash.
16. Hastings - Cabbage, potatoes.
17. Starke-Brooker-Lake Butler - Lima beans, snap beans, cucumbers, green peppers, potatoes, squash, strawberries.

WEST

18. Gadsden County - Pole beans, squash.
19. Escambia County - Potatoes.
20. Holmes-Jackson-Washington Counties - Watermelons, miscellaneous vegetables.

Commercial Vegetables Watermelons

FLORIDA: Usual Dates for Planting and Harvesting Vegetables, Melons, Potatoes, and Strawberries

Crop and Season	Planting Dates	Usual Harvest Dates		
		Begins	Most Active	Ends
Lima Beans, Spring 1/	Sept 15 - Apr 1	Nov 1	May 1 - June 30	July 15

THIS PUBLICATION INCORPORATES FINAL REVISIONS FOR THE 1958-59 THROUGH 1964-65 SEASONS, FOLLOWING ANALYSIS OF THE 1964 U. S. CENSUS OF AGRICULTURE, U. S. DEPARTMENT OF COMMERCE.

SEASONAL GROUPS--Seasonal estimates are made for most of Florida's vegetable, melon, potato, and strawberry crops to show supplies for a shorter period of time than the entire marketing season. The seasonal classification used for each of Florida's crops is shown on a previous page along with usual planting and harvesting dates.

PLANTED ACREAGE is the total acreage which has been planted for harvest during one designated season. To avoid duplication, acreage lost, and replanted to the same crop in time for harvest in the same season is counted only once.

HARVESTED ACREAGE is the acreage harvested or partially harvested plus any additional acreage which reached maturity, but was not harvested due to labor shortages, low prices or other economic conditions. Acreage lost before or at maturity through natural causes is not included in the acreage for harvest.

YIELD is the average production of merchantable quality produced per acre and includes any unharvested production left in fields for economic reasons.

PRODUCTION includes the quantity actually harvested plus any quantity that was left due to economic abandonment.

ECONOMIC ABANDONMENT is that portion of the crop that reached maturity and is of merchantable quality but was not harvested because of labor shortages, low prices or other economic factors.

PRODUCTION OF VALUE is that total production less the quantity abandoned due to economic reasons.

UNIT VALUE for production sold on the fresh market represents the F. O. B. price received or its equivalent for all grades and quality of the commodity including selling charges. Unit value for quantities sold to processors for the 1963 fall crop and all prior seasons, represent prices paid the grower at the first receiving point. Since that time, value is on a delivered to the processing plant door basis and includes transportation cost, etc.

TOTAL VALUE is the value of production sold. It excludes economic abandonment, cullage, and any portion of a crop not harvested.

RAIL - TRUCK shipments are included in the straight rail shipments shown for each crop.

RAIL LOAD FACTORS -- Represents the average number of packages per rail car based on tabulations of way-bills showing the contents of each car.

MIXED RAIL CARS -- For major commodities the quantity shipped in mixed rail loads is tabulated from way-bills. The total quantity of each commodity is then converted to the equivalent of a straight rail car load.

TRUCK SHIPMENTS are converted to equivalent carlots on the basis of a predetermined load factor. A minor difference of carlot equivalents in the season total obtained by adding the monthly or weekly shipments may exist because of rounding.

PRODUCTION AND PRICE UNIT -- The official USDA vegetable crop estimates are published on a weight basis. For this bulletin the official estimates for most vegetable crops have been converted to the most commonly used container. The following table gives the net weight used per container and the number of containers per hundredweight.

PRODUCTION AND PRICE UNIT
Most Common Unit, Estimated Net Weight, Number of Units per Hundredweight,
Principle Vegetable Commodities, Florida, 1967-68 Crop Season

Commodity	Unit	Est. Net Weight	No. of Units per Cwt.	Commodity	Unit	Est. Net Weight	No. of Units per Cwt.
		Pounds				Pounds	
Lima Beans	Bushel	32	3.125	Escarole	Crate	25	4.000
Snap Beans	Bushel	30	3.333	Green Pepper	Bushel	28	3.571
Cabbage	Crate	50	2.000	Potatoes	Sack	100	---
Celery	Crate	60	1.667	Squash	Bushel	42	2.381
Sweet Corn	Crate	42	2.381	Strawberries	Flat	10.25	---
Cucumbers	Bushel	52	1.923	Tomatoes	Crate	40	2.500
Eggplant	Bushel	33	3.030	Watermelons	Cwt.	100	---

Florida vegetables, melons, potatoes and strawberries marketed during the 1967-68 season were estimated at 45,659,000 hundredweight, 3 percent more than was marketed the previous year, but nearly 5 percent less than in 1965-66. Total sales were estimated at $294,579,000, compared to $256,416,000 the previous season, and $257,044,000 during the 1965-66 season. Vegetable sales were up an estimated 16 percent, or nearly 35 million dollars more than in 1966-67, and 20 percent more than sales during 1965-66. Melon sales were down about 1.5 million dollars and strawberries were down about 1.4 million dollars in comparison with 1966-67. Irish potatoes sold slightly cheaper, but yields were the highest of the last 3 years. Sales during 1967-68 were $6,282,000, or nearly 38 percent more than sales from the previous year's light crop, but only 4 percent more than the 1966 sales.

Weather conditions during the fall were favorable for heavy production. Shipments through December 30 converted to hundredweight were 42 percent more than in the previous fall and 37 percent more than average (1963-65).

Florida vegetable farming is a continuing operation. Preparation for the 1967-68 crop was underway before harvest of the 1966-67 crop was complete. Land clearing, ditching and diking were active. Celery and eggplant seedbeds were planted for late July and August transplanting. By September 2, the equivalent seeded acreage of tomatoes was approximately 16,900 acres. This is the most important early crop planted. Seeding of sweet corn began in early August and by mid-August, weekly plantings had become significant -- all in the Everglades mucklands. Beans for early fall fresh market and processing were being seeded, beginning in late August in West and North Florida, and at Pompano by mid-September. The South Peninsula was subjected to rather excessive recurring rains from late September into mid-October. Hurricane Beulah by-passed Florida, crossing the Gulf to the Rio Grande Valley instead. Cold of November 19-21 brought a general frost to North Florida and terminated harvest of most remaining vegetables. Since the late October rains, an extremely dry period was experienced by much of Florida, until broken December 11. Up to that time, most transplant "live" was dependent upon applied moisture. December temperatures were above normal until the 25th when minimums were in the 30's and 40's over the Peninsula. Gusty winds accompanied the cold front.

Seeding of watermelons got underway in late November in the important Immokalee area. On Friday, January 26, frost and freezing temperatures were general. Low temperatures ranged from the low 20's in the north to the mid 30's in the Everglades and the Lower East Coast. Colder locations were lower. As low as 32 degrees was reported southward into the farming area of Homestead. The Everglades had frost quite general at most locations away from the Lake. Central and North Florida crops had become fairly well acclimated.

During the week ending February 10, cold again occurred over an area parched from drouth. Snow flurries were observed in Central Florida on the night of the 7th. Recurring cold and dry weather continued to prevail until the week ending February 24 when rainfall was abundant in all sections of the State, except for a few places along the Lower East Coast. Most drouth-stricken areas now had adequate moisture. Most crops were well acclimated and the rather general frost throughout North and Central areas February 25 and 26 generally retarded growth. However, transplanted peppers in Central Florida were damaged severely and had to be reset heavily. Tomatoes in West Central and North Central areas had become toughened and most came through. Most potato plants in Hastings where emerged were damaged February 13 and again the 25. On the average, this was the coldest February since 1958, and one of the coldest on record in Florida.

Again, on March 25, frost formations occurred but were variable, generally light to moderate. West-Central Counties had lows of 33 degrees. Spot replanting was necessary at Webster but frost disappeared at Plant City before sun-up. Zellwood reported 32 degree weather with no frost, but 28 degrees the following morning brought a little frost and considerable ice. Hastings potatoes were again frosted as were those north of Gainesville. The acreage damaged was relatively small. By the third week of April, planting was confined to corn and celery, primarily in the Zellwood area. Dry weather prevailed and irrigation really saved crops in all areas. By the last of the month, locally heavy showers occurred in North Florida and along the Central East Coast, but little relief from the drouth was felt in most of the Peninsula. Showers were mostly light and scattered. Harvest had begun on potatoes in Hastings and by the 10th of May, the area was moving into full volume. By the third week of May, shower activity began a more rapid termination of harvest in some areas, especially in South Florida. Rains were heavy in the Everglades the week of May 20-26 with 8.8 inches reported at the Experiment Station. By this time, corn and tomatoes made up 62 percent of the vegetables shipped. Watermelon shipments increased 27 percent this particular week. However, potato shipments at Hastings declined the same week 11 percent.

In early June, most producing areas were in seasonal decline. Remaining tender vegetables were primarily confined to Central and North Florida. Out of season Hurricane Abby curtailed harvest appreciably in Central areas because of the heavy tropical storm rains. By the third week of June, harvest was confined to sweet corn, celery, eggplant and peppers, primarily in Central and West Florida. Potato harvest was finishing up at Hastings and watermelon shipments had passed peak volume. Sweet corn continued available at Zellwood and nearby mucklands through July 10, and watermelons in North and West Florida continued of good quality but volume had decreased sharply. After this, various summer vegetables constituted most of Florida's vegetable supply and the season was ended.

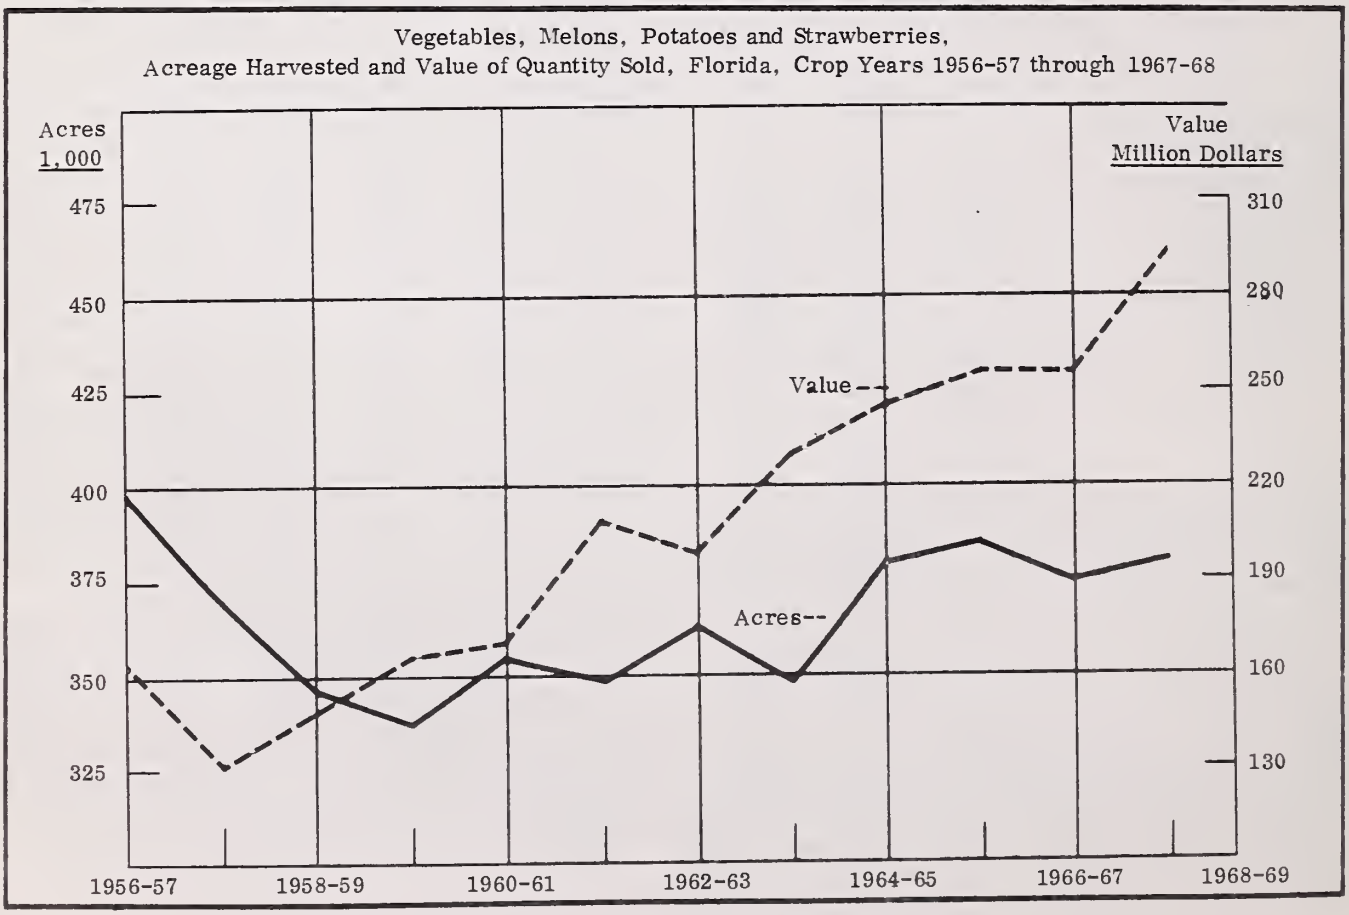
1/ Vegetable crops include Lima Beans, Snap Beans, Cabbage, Celery, Sweet Corn, Cucumbers, Eggplant, Escarole, Lettuce, Green Peppers, Squash, and Tomatoes. Cauliflower is included 1949-50 through 1960-61. Spinach is included 1955-56 through 1967-68. Other vegetables are included 1960-61 through 1967-68.



During 1967-68 an estimated 69,000 bushels of lima beans were produced and harvested for fresh market from 900 acres, the same as the acreage harvested the previous season. Value of beans sold was $312,000 compared to $351,000 during 1966-67.

Processing limas of any variety for commercial pack would be in addition to the fresh estimated here. Since the known acreage for processing was utilized by less than three firms the acreage and production was included in miscellaneous crops.

Limas include Fordhook limas, baby limas, and speckled butterbeans. Early harvest began in North Florida and the Plant City area during October, then shifted to Pompano for a light harvest through the winter and early spring. Heaviest production is in the spring and consists of widely scattered small acreages. A high percentage of the beans produced was consumed within the State. All acreage is included in one annual estimate, classified Spring. Interstate shipments are no longer reported daily. Separations from miscellaneous vegetables at the end of the season indicate 28 carlots moved interstate. Heaviest movement was during May and June.

There is some interest in contract beans for processing. Florida production is expected to continue light until such time as a demand for shelled, fresh market or processing beans may increase substantially.

Production of Florida snap beans during 1967-68 was estimated 5,956,000 bushels, about 7 percent more than was produced during the previous crop year. Of this production, 4,677,000 bushels were marketed fresh at an average value per bushel of $3.77 or 9 cents less than the previous year's average. Processors utilized 1,152,000 bushels at an average price of $1.67 per bushel. An estimated 127,000 bushels were left in the field due to economic reasons. The combined sales totaled $19,554,000, only $49,000 more than the previous season. The winter period (January, February and March) averaged $4.56, a sharp increase over the fall and spring average prices.

The Pompano area produced 44 percent of the State's volume. Bush varieties, heavy to round green beans, with a few yellow wax, were grown. Planting began in mid-September and continued into late March. Harvesting was continuous from late October into early May. Dade County produces lesser supplies of bush beans with some contracted for processing. The Everglades area produces mostly fall and spring crops. Bush varieties are grown with considerable acreage contracted for processing. Practically all production from the Zellwood mucklands fall crop was utilized in processing. Rather limited acreages for fresh market are grown, fall and spring, at Sanford, Plant City and in North Florida. In North Florida, interest is increasing in production for processing. Losses were heavy in the Hastings spring area experimental acreage for processing.

Pole bean production began in the early fall in Gadsden County of West Florida. Plantings were heavy to 191 varieties. Fall production was heavier than spring production mainly because of labor conservation for work in shade tobacco. Plant City also grows fall and spring pole beans, heavy to 191 variety. Neither of these areas compare with the large acreage grown over a long period in Dade County, where 5,790 acres produced an estimated 1,586,000 bushels, of which 1,558,000 were marketed. Harvest began in late October and continued into the first week of May with peak production near the end of the season, or in late April. Plantings ran heavy to McCaslan and Dade varieties.

Crops in various areas were subjected to inclement weather as presented in the opening summary. The favorable weather following fall rains was conducive to heavy yields, highest of record, averaging 146 bushels per acre; pole beans, included, averaged higher than bush beans. State average yields were surprisingly similar the last 3 years, averaged approximately 123 bushels per acre -- all varieties and types of harvest. Pole beans are all harvested by hand. More and more bush beans are harvested mechanically.

CABBAGE
1967-68

Cabbage produced and marketed during the 1967-68 season in Florida was estimated at 7,820,000 crates. This is a record marketed but the 1950-51 season produced slightly in excess of this. An estimated 17,600 acres were planted, of which 17,000 were harvested. Yields were outstanding. Generally favorable weather and the increase in hybrid varieties grown produced 460 crates per acre.

Sales were mostly good. A combination of bags and crates for the entire season averaged $1.75 per unit. December, April and June were the lowest monthly averages. January, February, March and May ranged from $1.80 to $2.00. The total value of the crop was $13,685,000, up 28 percent over the previous crop.

Most cabbage grown in Florida is transplanted with plants grown in local seedbeds. Some early season plants are grown in Georgia and the Carolinas. A small early acreage is seeded direct to the field in the Zellwood muck soils, and considerable acreage is seeded direct to the field in the Everglades. Earliest harvest was from the direct seeded acreage at Zellwood, followed by light harvest from early transplanted acreages. The Hastings area increased plantings over the previous year appreciably, especially for early harvest. These early cabbage caused a heavier percentage of the total shipments to move in December than in previous years. A hurricane disaster in the Lower Rio Grande Valley of Texas prevented heavy supplies at this time from that area, and demand for Florida cabbage was better than normal. The important Hastings tri-county area planted a total of 8,200 acres and produced an estimated 48 percent of the State's total production. Harvest was continuous in this important North Florida area through April, but declined rather sharply during April. Harvest continued in Central Florida into early June. This area transplants later in the season than others of the State, continuing into early March. The adverse weather that occurred from time to time (whether from rain, cold, frost or gusty winds) resulted in relatively minor damage, all things considered. The heaviest losses, percentage-wise, were in the Everglades area. The recurring cold of February, though record-breaking in its deviation from normal, had acclimated plants so that little damage occurred. Mostly, growth was slowed, curtailing harvest in some cases. The spring drouth prevented sizing in late fields of Central Florida. Some harvested very light, or not at all.

Florida produced 22 percent less cantaloups this season than last. Acres harvested was the same as last season, 1,000, but yield was down to 70 hundredweight per acre from 90 last season. Total crop value was almost the same at $469,000. Value per unit was up 29 percent to $6.70 per hundredweight.

North Florida produced 33 percent of the total crop on 39 percent of the harvested acres. West Central counties produced 21 percent of the crop while the Southwest area produced about 17 percent.

Limited replanting was necessary in North and Central areas following cold and wind in February and March. Harvest began in the southwest area in April and progressed up the State. About 68 percent of the total crop was moved in June.

The gross value of Florida celery during 1967-68 was $22,336,000, compared to $19,192,000 the previous year. The average value per crate was $3.08 for the 1967-68 season, an increase of 59 cents over the previous season's average. Growers planted 12,400 acres compared to 13,000 the previous year.

The crop is grown exclusively in four areas. The Everglades is the principal area of production with 79 percent of the state's planted acreage. Supplies were available from late October through mid-June. The other producing areas are Central Florida, Sarasota and Island Grove. Cutting began at Zellwood November 6, and was terminated in mid-December to start again in late April and continue into June. The sandland crop at Sanford was harvested primarily during January, February and March. Harvest from Oviedo muckland started in early January and continued through late May. Harvest at Sarasota is primarily during January, February and March but a light production continued into late May. Celery in the Island Grove areas is grown in the muckland soils of Alachua County. Harvest in the Island Grove area was during April, May and June. The crop is generally very hardy and will withstand the extremes of weather quite well.

The Florida Fresh Fruit Exchange administrates the celery marketing order. Their field supervisors provide planting, harvesting, and production data. In cooperation SRS assembles these data into weekly and monthly reports to the participating industry.

Most acreage lost by natural cause was attributed to adverse weather. The 500 acre loss was in the spring crop, partly from bolting. Marketing conditions necessitated economic abandonment of otherwise marketable celery during both seasons.

Florida growers marketed 9,644,000 crates of sweet corn during 1967-68, 9 percent less than the record 10,638,000 crates produced and sold during 1966-67. Value of sales at $24,744,000 was only 6 percent less than those of the previous crop year, hence the average value per unit was higher - $2.56 compared to $2.47 in 1966-67.

Of the 59,500 acres planted only 53,600 were harvested, or 2 percent less planted and 4 percent less harvested than in the previous crop year.

Planting for fall harvest was almost exclusively in the Everglades mucklands and began in early August. Harvest got underway in early October, and with weather conditions generally favorable, volume increased until late November. As supplies declined in late December, harvest began at Pompano and continued through April. Production from this important winter and early spring area was supplemented by supplies from the Ft. Myers-Immokalee and Dade County areas. Harvest was active at Ft. Myers in mid-January but Dade County did not start until early March. Cold weather had a general retarding effect on growth and maturity.

Spring plantings in the Everglades were seriously damaged by the late February freeze. Considerable acreage was lost and replanted. This area came into spring harvest in April and continued until terminated by heavy rains in early June.

Seeding started at Zellwood about the first of March. Harvest started in late May. Volume supplies were available most of June. Harvest continued into early July. Early June rains from Hurricane Abby were adversely affective. Some acreage was lost.

Other minor producing areas are located in West Central, North and extreme West Florida. Harvest from these areas occurred in the spring months.

Florida cucumber production increased to 3,808,000 bushels during 1967-68, 21 percent more than the previous crop year. This increase was harvested from only 11 percent more acreage, since yields were up 9 percent. Value per unit averaged $3.40 per bushel, forty-six cents less than the previous year's average. This 21 percent increase in production with its reduced average price sold for $12,962,000, only 6 percent more than gross value of the previous crop.

Pickle cucumbers utilized in saline and sterilized process are estimated separately and are excluded from these data but are included in miscellaneous vegetables.

Cucumbers are especially adapted to sandy soils, and are grown in practically all vegetable areas except Florida's mucklands. The Southwest Counties or the Ft. Myers-Immokalee area grew 46 percent of the State's harvested acreage. Shipments from this area began in October and attained full production for fall in November and December. Supplies were gradually decreasing during January to very limited in February. Cold damaged plants on several occasions. Spring harvest began, very light, in early March, but built up to peak proportions in April and early May.

West Central Counties produced heavily in the early fall and mid-spring. Principal center of supply was the Wauchula area.

Dade County and Pompano-Martin areas produced over a wide period with heaviest volume in late fall and early spring, but with a definitely light trend in January and February. Low temperatures and cold winds affected crops along the Lower East Coast throughout the winter. Growth was slow and some replanting was necessary. Peak movement was reached in May. The Pompano marketing center drew cucumbers from a wide area, being headquarters for a large portion of the buying element of the industry. Included in shipments from this area were most imports into Florida for repacking and distribution.

North-Central areas, heaviest at Samsula-Sanford, Webster and Zellwood grew both fall and spring table stock and pickles. Pickles moved into fresh (O'Nite dill) channels and for regular pickle processing. North Florida had widely scattered plantings of table stock in the fall with a heavier concentration of table stock and pickles in the spring. Harvest began in May and extended into June, closing out the Florida season.

Florida's eggplant production declined 17 percent from the previous crop year, to 976,000 bushels. A yield of 71 bushels per acre less than the previous season was mainly the reason for this lower production, as only 100 acres less than last year were harvested. Average value at $3.19 per bushel pushed total value to $3,116,000, 15 percent greater than the previous year.

Eggplant was shipped from Florida every month of the 1967-68 season with peak movement in December and May. Heaviest volume came from the Pompano area with lesser quantities, fall and spring, from other areas of the state.

By September, harvest of eggs was underway in North and North Central areas. By the end of October most areas were harvesting. The Pompano area suffered considerable rainfall during October which washed beds and caused some loss of fertilizer. Disease control became a problem and pack-out was reduced.

Dry, windy weather was beneficial to the Pompano area in December as shipments reached fall peak. Frost on November 19-20 practically ended production in North Florida. Central Florida and Ft. Myers-Immokalee continued harvesting ample supplies.

Supplies from the Pompano area continued steady throughout the winter season. Wind damage and bloom drop became severe in March as cold weather prevailed. Supplies became available from the Ft. Myers-Immokalee area in mid-April and from Plant City in mid-May. Rains in South Florida in mid-May lowered quality and reduced pack-out especially in the Pompano area. By June, Pompano supplies were decreasing as scattered plantings in North and Central Florida began to reach volume. Supplies from these areas closed out the season in July.

Escarole and chicory or endive production in Florida during 1967-68 was estimated at 3,184,000 crates of which 3,024,000 crates were sold, compared with 3,080,000 crates the previous season. Only 6,600 acres were planted compared to 7,500 the previous year. The 5,900 acres harvested was 1,100 acres less than was harvested the previous year. The lighter production sold well and averaged $1.92 per crate, 57 cents more than the $1.35 average for the previous year. The crop was valued at $5,821,000.

The crop is grown primarily in muck soil. Harvest stretches over a long period from late October through early June. The Everglades is the major producing area with 63 percent of the planted acreage. Light seeding began in early September and gradually increased as the season advanced. By early October thinning of first plantings was active and light harvest began later in the month. Weather was favorable during the early fall months. However, rain and fog coupled with warm days in mid-December were detrimental to older plantings. The cooler weather during the winter months was generally beneficial except for occasional frost burn. Harvest began declining after mid-April and continued in a limited way through May. Zellwood is the second area of production with generally two periods of heavy harvest. The first period began in late October, increased to volume by early November and started declining in early December. The second period of heavy production began in early April, increased to volume by late April and continued into early June. Some acreage was planted on sandland between muck pockets as an insurance of supply, since muck soils are more susceptible to low temperatures than the nearby warmer sands.

The economic abandonment shown was reported in the Everglades and at Zellwood.

Florida lettuce production for the 1967-68 season was 360,000 cwt. compared to 351,000 cwt. the previous crop year. The 4,800 acres planted was an increase of 300 acres over the previous year. Production was valued at $3.492,000. Nearly 52 percent of the crop was planted in the Everglades; North Central planted 18 percent and West Central 16 percent of the crop.

Heaviest production was in Romaine lettuce followed by Boston, Iceberg, leaf lettuces and Bibb. Intrastate consumption is rather heavy especially Iceberg and Bibb varieties.

The Everglades maintains a relatively steady volume from early November through mid-May. The crop was rather susceptible to extremes of temperature which caused seeder formation. The cool weather during the winter months was generally beneficial and seeder formation was, in general, a minor problem. The crop was quite variable in quality and quantity. Zellwood production was heaviest during the fall and spring months. Early harvest for local market began during October. Harvest increased to volume supplies through November and then declined to light during midseason, but increased in early April. Supplies continued available through late May and then declined rapidly. Various varieties are also grown on the warmer sandlands in the area as the muck soils are more susceptible to cold. Supplies from these two areas are supplemented by lesser acreages through Central and South Florida.

Pepper production for 1967-68 was estimated at 6,572,000 bushels compared to 5,775,000 bushels produced during the previous year. The 17,100 acres planted were only 100 acres more than 1966-67 acreage.

The total value at $25,790,000 was 27 percent more than the previous crop's value. The major producing area, made up mainly of Broward, Palm Beach East and Martin Counties, grew 44 percent of the production. About 42 percent of the production was grown in the southwestern areas on 40 percent of the total planted acreage.

Most of the South Florida crop is directly seeded in the field and planting began in August. In the Ft. Myers-Immokalee area, dry weather curtailed some early seeding. There seeding continued through the fall months and terminated by early January. Heavy rains in late September and early October flooded low spots in fields and caused damping off in some plants. Hail during the fall season necessitated spot resetting. Early harvest commenced in mid-November with quality and size improving as the season advanced. Supplies remained relatively steady during the winter months. Plants were subjected to recurring cold spells but most recovered favorably. Early spring's hot weather followed by frequent heavy rains characterized that season. Harvest was terminated in June in this area by the arrival of Hurricane Abby.

In the Pompano-Martin area, seeding continued into December. Recurring rains in the fall washed seedbeds, leached fertilizer and caused some root damage. Harvest of bell peppers started in mid-November but hot varieties were available earlier in the season. During the winter, winds and cold temperatures caused lower plant condition but steady, strong supplies remained available. Peak harvest occurred in April. Decreasing supplies were available until Hurricane Abby curtailed harvesting.

A small acreage grew in Central Florida during the fall season but harvest was in the clean-up stage by December. Transplanting from seedbeds was underway in the Webster area during January, while most plants in other northern and Central areas remained in these protection units until late March. Considerable resetting was necessary in the Webster area because of the recurring extremely cold weather. Harvest began in the Central area in early May and supplies peaked during the first of June. Only limited supplies were available into July from the northern areas.

Florida growers produced 6,767,000 hundredweight of Irish Potatoes in 1967-68, valued at $22,991,000. Production was nearly 42 percent more than that of the previous year which was seriously damaged by freeze and prolonged shower activity. It was a record crop, though exceeded in 1957. Although total value was 38 percent greater than the year before, the price per cwt. was down only 10 cents.

Florida production is divided into 3 seasonal groups -- winter, spring-Hastings, and spring-Other. The earliest producing area of winter potatoes is in the Everglades mucklands, where a small acreage of "reds" and "whites" began harvesting in December and finished in late January, or about the time Ft. Myers began to dig their early "reds". Harvest of "reds" began in Dade County the first half of February where 7,650 acres (including about 15 percent "whites") were planted and harvested. Harvest of "whites" in the Ft. Myers-Immokalee area began as "red" harvest was being completed, or during early March. It is obvious that South Florida potatoes, though harvesting in April, are all considered winter crop. There is an overlapping between completion of winter harvest and beginning spring harvest.

The Hastings 28,300 acres planted for spring compared with 30,000 in 1967. The 27,400 acres harvested was 27 percent more than the previous year. Losses in 1967 resulted from adverse weather, as stated above. Losses in 1968 were because of June rains. The Hastings crop is planted heavily to white-skinned varieties for the potato chip industry. A good portion of the crop is contracted for this purpose. Late planting and weather conditions delayed the crop about 2 weeks. Below freezing temperatures on February 12-13 burnt some young plants, rather severely in Flagler County. February 25-26 frost, the same date as the severe freeze of 1967, further set back growth and potential harvest. A few potatoes were dug here the third week of April, and the first "reds" were dug in early May. The bulk of the crop was harvested during May, and through June as weather permitted. Average price per cwt. (all grades, sizes and types of sale) was estimated at $3.16.

Harvest of spring-Other began early in the Sun City area of Hillsborough County with a few dug in March, but quite active through April into early May. Scattered plantings across Central Florida were also dug in April. Other producing areas of this seasonal group were the late crop in the Everglades, and in North and West Florida. Most of the West Florida crop markets through Atmore, Alabama.

SPINACH FOR PROCESSING
1968

Spinach for processing was grown in the mucklands of Orange and Lake Counties. Harvested acres declined to 1,900 from 2,200 the previous year. The 186,000 tons useable spinach delivered to plants was valued at $391,000, 28 percent less than the previous winter.

Value per unit was based on useable spinach delivered to the processing plant door. Most Florida spinach was utilized by plants located in Florida, Georgia, and Alabama.

Planting got underway in November and harvest was completed by March. Frost from time to time is desirable to control weeds. Early spinach was subjected to warmer weather than desired. An estimated 200 acres were lost.

Spinach for Processing: Acreage, Production, and Value in Florida, Crop Years 1959 through 1968

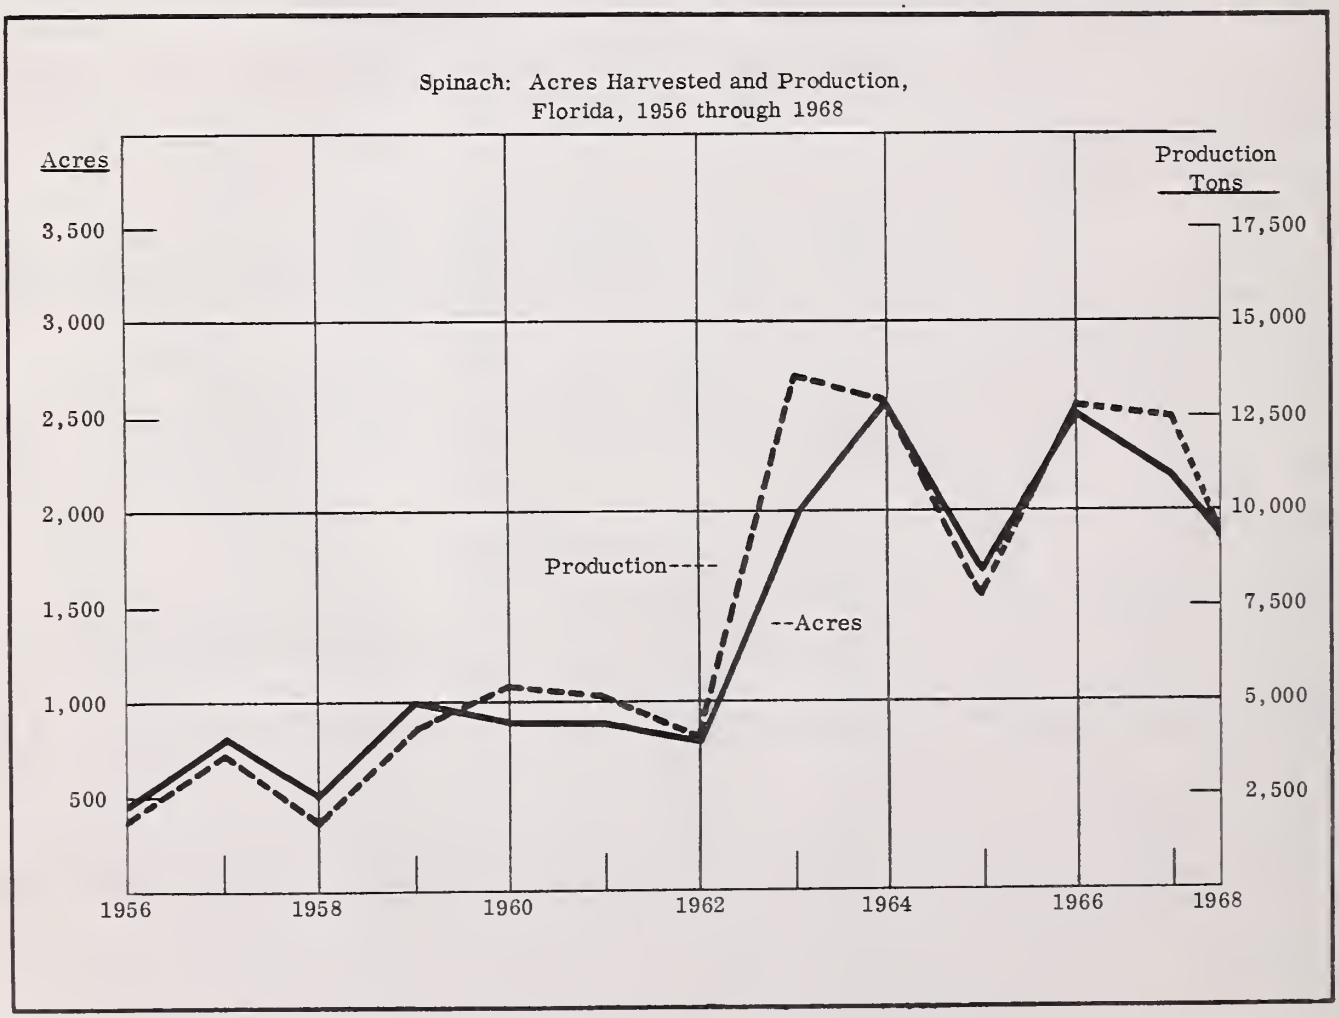
Spinach: Acres Harvested and Production, Florida, 1956 through 1968



Florida produced 1,417,000 bushels of squash, about 18 percent more than during the 1966-67 season. The 9,200 acres planted was up only about 6 percent more than the previous year. This crop's sales value was estimated at $6,103,000, making the average price of $4.31 only $0.06 more than the previous season's average price. Slightly more than 56 percent of the planted acreage was located in the southeastern area. The entire southern part of the State, accounting for 75 percent of the planted acreage, harvested 80 percent of the total production.

Shipments were from September until June. Except for the extremely small percentages in September 1967 and June 1968, most months showed even distribution with the highest movement of 16 percent in April.

Harvest continued during the fall season in the northern and Central areas of the State until terminated by frost and cold weather late November and in December.

The principal market outlets for the important Lower East Coast were in Pompano and Homestead. Yellow crookneck varieties dominated the plantings in Dade County. During January that area became the principal source for yellow crookneck squash. Dade and Pompano areas supplied the majority of the crop with only limited supplies from the Immokalee area during February.

Planting was active during March into North Florida. Frost in late March damaged plants and slowed germination in Central and North Florida.

First spring cuttings occurred in the Plant City area in mid-April. All varieties were available but ran heavily to yellow crooknecks. Statewide spring harvest declined sharply in mid-May but continued very limited into early June.

Production of Florida strawberries has decreased almost 50 percent from the peak 1964-65 season. Total value received for the crop at $4,358,000 is 46 percent less than that same season, and 25 percent less than the 1967 crop.

From last year, production declined 14 percent, harvested acreage 5 percent, and yield 9 percent.

About 46 percent of the production came from the Plant City-Palmetto area and 36 percent from the Lower East Coast. The rest is grown in scattered areas in Central and North Florida. Shipments in March accounted for 41 percent of the total with April moving 30 percent.

Harvesting began in December in the Plant City and Lower East Coast areas. Warm weather lowered yields on the Lower East Coast as supplies remained light through February. Mid-twenty temperatures in North Florida froze fruit and bloom in mid-January. Some growers saved berries by sprinkling.

Supplies continued light through February and increased sharply in March. Peak volume was reached in late March - early April. The Lower East Coast and Plant City areas completed harvest in late April as North Florida continued with light supplies into May.

During the 1967-68 season, Florida produced an estimated 17,817,000 equivalent forty-pound crates of fresh tomatoes from 47,000 harvested acres. The F. O. B. price averaged $5.05 per crate. An additional 3,430,000 equivalent forty-pound crates, utilized by processors, averaged $0.64 per crate delivered to the canning plant. The entire crop was valued at $92,159.000.

Tomatoes for mature green harvest, one of the two categories of Florida's crop, represented 89 percent of the total 47,800 acres planted in 1967-68. Acreage for vine ripe harvest, the other category, yielded 850 forty-pound units per acre from 5,300 harvested acres. This 11 percent of the total acreage; accounted for 25 percent of the total fresh production. This acreage was primarily located in the Immokalee-Naples and Pompano-Martin areas.

Most vine ripes are packed in twenty-pound units with a small amount of selected sizes and quality packaged in eight-pound flats. Most mature greens are packed in forty-pound units.

Generally ideal weather - mild, warm days and cool nights, characterized the fall growing season of 1967-68. Frost and freezing temperatures occurred for the most part in the northern and western sections of the State, therefore had little adverse effect on the majority of the acreage. The cold, dry period during the winter allowed maximum harvest of the reduced acreage. The spring crop was damaged because a warming trend did not develop until late March. Drought, compounded by sharp cold periods, prevailed through much of the early spring. Harvest terminated in late May by rains preceding tropical storm Abby.

Processing tomato harvest followed the completion of fresh market harvest and supplies were available into early July.

1/ Osceola included 1967-68. 2/ Charlotte included 1965-66 through 1967-68. 3/ Martin included 1967-68.
4/ Broward included 1967-68.

Florida produced 7,560,000 hundredweight of watermelons during 1968 from 56,000 harvested acres. At $2.10 per hundredweight, the total value, $15,876,000 was 9 percent less than the 1967 season's value. Earliest harvest began in mid-March in the Immokalee area. These southwestern counties with only 17 percent of the planted acreage produced about 31 percent of the total production. Other South Florida and West Florida produced 16 percent and 13 percent, respectively. The northern and Central areas accounted for about 50 percent of the planted acreage and produced 40 percent of the total harvest.

Planting started in late November in the Immokalee area and finished in January. Other areas began seeding in January and planting progressed northward until the entire crop was in the ground by early April. During January young plants in the Immokalee area discolored because of cold weather but recovered well. Winds and extremely cold weather during February declined plant condition and damaged young fruit. During this period replanting occurred in most northern and Central areas because of the adverse weather. Germination and growth were slowed. Frost and freezing temperatures in March resulted in losses of whole fields in some northern and Central areas. Plants in these areas were subjected to a prolonged drought during their early growing period. The dry weather continued through most of the spring and extended into West Florida.

Harvest reached peak volume in late May in the Immokalee area as light supplies became available northward into the Central areas. Peak supplies became available during mid-June in the northern counties. Quality and size were very good in most of these northern and western areas where irrigation offset the early drought effect. Because cold, adverse weather slowed maturity, many areas came into volume production simultaneously and created an acute transportation shortage.
